Pharmacokinetic Study of Cefazolin  
Used Prophylactically in Canine  
Surgery for Susceptibility Testing  
Breakpoint Determination.  
Front. Pharmacol. 9:1137.  
doi: 10.3389/fphar.2018.01137

This study aimed to determine the population pharmacokinetic (Pop PK) parameters of cefazolin administered prophylactically at 25 mg/kg intravenously (IV) 30 min before surgery in a canine population of 78 dogs and assess whether covariates, such as sex, age, body weight (BW), breed, health status, creatinine level, and surgery time, have an influence on cefazolin disposition. The ultimate goal was to compute PK/PD cut off values and subsequently establish a specific clinical breakpoint (CBP) for the development of an antimicrobial susceptibility test (AST) of cefazolin in dogs according to the VetCAST approach. Two to 11 blood samples were collected from each dog from 5 to 480 min after cefazolin administration. A two-compartment model was selected, and parameterization was in terms of serum clearance (CL), intercompartmental CL(s) (Q) and volume(s) of distribution (V). The percentage of cefazolin binding to serum protein was  $36.2 \pm 5.3\%$ . Population primary parameter estimates  $V_1$ ,  $V_2$ , CL, and Q were (typical value  $\pm$  SE)  $0.116 \pm 0.013$  L/kg,  $0.177 \pm 0.011$  L/kg,  $0.0037 \pm 0.0002$  L/kg/min, and  $0.0103 \pm 0.0013$  L/kg/min, respectively. Cefazolin presented rapid distribution and elimination half-lives (mean  $\pm$  SE)  $4.17 \pm 0.77$  min and  $57.93 \pm 3.11$  min, respectively. The overall between-subject variability (BSV) for estimated primary parameters ranged from 36 to 42%, and none of the seven explored covariates were able to reduce this variability by an amplitude clinically relevant. By Monte Carlo simulation, the probability of a PK/PD target attainment (here to achieve a free serum concentration exceeding the MIC for 50% of the dosing interval in 90% of dogs) was computed with a dosage of 25 mg/kg administered IV every 6 h for 4 administrations in 24 h. The computed PK/PD cut off value was 2 mg/L. In conclusion, cefazolin administered prophylactically in surgical dogs at 25 mg/kg IV every 6 h was deemed effective against pathogens with a MIC value  $\leq 2$  mg/L and from a PK/PD perspective, can be recommended in a wide range of canine patient populations with no necessary dose adjustment for special dog subpopulations.

**Keywords:** cefazolin, dog, prophylactic administration, surgery, population pharmacokinetics, PK/PD cut off value

The dosage regimen used for PK-PD analysis of cefazolin was 25 mg/kg administered every 6 hours IV in horses and dogs.
					≤ 17	≤ 2	4	≥ 8	See comment (26).		

Cefazolin breakpoints were determined from an examination of MIC distribution data and PK-PD analysis of cefazolin. The dosage regimen used for PK-PD analysis of cefazolin was 25 mg/kg administered every 6 hours IV in horses and dogs.

## Conclusion:

- At a dose of 25 mg/kg IV every 6 hours, the PK/PD cutoff value was 2 µg/mL.
- No changes necessary based on age, surgery, health status, weight, creatinine, and time.
- “The present trial is consistent with CLSI breakpoint.”

# An evaluation of serum gentamicin concentrations and bacterial susceptibility to gentamicin in equine practice

Andy E. Durham

Liphook Equine Hospital, Liphook,  
Hampshire, United Kingdom

**Correspondence**

Andy E. Durham, Liphook Equine Hospital,  
Liphook, Hampshire, GU30 7JG,  
United Kingdom.  
Email: andy.durham@theleh.co.uk

**Background:** Therapeutic drug monitoring and minimum inhibitory concentration (MIC) data allow more informed use of gentamicin.

**Hypothesis/Objectives:** To measure peak and trough serum gentamicin concentrations in horses after a 6.6 mg/kg dose of gentamicin given IV and the MIC of gentamicin of bacteria for which gentamicin might be selected.

**Methods:** Retrospective analysis of hospital records. Peak and trough plasma gentamicin concentrations were measured after 6.6 mg/kg gentamicin IV in 339 hospitalized horses. The MIC of gentamicin was measured for 503 isolates from ambulatory practice and 33 from hospital practice. The distribution of gentamicin concentrations and MIC results were compared to current recommendations for MIC breakpoints.

**Results:** The median serum gentamicin concentration at 60 minutes after administration ( $C_{60min}$ ) was 21.4  $\mu\text{g/mL}$  with a distribution indicating that bacteria with  $\text{MIC} \geq 2 \mu\text{g/mL}$  were unlikely to be exposed to sufficient gentamicin for effective killing. Approximately 90% of isolates from ambulatory practice and 36% of hospital isolates had MICs at or below breakpoints for susceptibility with most of the remainder unlikely to be responsive, even to higher IV doses.

**Conclusions and Clinical Importance:** Gentamicin at a dosage of 6.6 mg/kg IV is likely to be effective against the majority of infections encountered in ambulatory practice, but less effective in an equine hospital. Because there was a dichotomy of most bacteria as being clearly susceptible or clearly resistant to gentamicin, it appears unlikely that higher doses would have been more efficacious, especially in the hospitalized population in our study.

## An evaluation of serum gentamicin concentrations and bacterial susceptibility to gentamicin in equine practice

### Study Design:

- 339 hospitalized horses.
- MIC measured from 503 isolates in ambulatory practice and 33 from hospitalized horses.
- Dose: 6.6 mg/kg once daily.

**Background:** Therapeutic drug monitoring and minimum inhibitory concentration (MIC) data allow more informed use of gentamicin.

**Hypothesis/Objectives:** To measure peak and trough serum gentamicin concentrations in horses after a 6.6 mg/kg dose of gentamicin given IV and the MIC of gentamicin of bacteria for which gentamicin might be selected.

**Methods:** Retrospective analysis of hospital records. Peak and trough plasma gentamicin concentrations were measured after 6.6 mg/kg gentamicin IV in 339 hospitalized horses. The MIC of gentamicin was measured for 503 isolates from ambulatory practice and 33 from hospital practice. The distribution of gentamicin concentrations and MIC results were compared to current recommendations for MIC breakpoints.

**Results:** The median serum gentamicin concentration at 60 minutes after administration ( $C_{60min}$ ) was 21.4  $\mu\text{g/mL}$  with a distribution indicating that bacteria with  $\text{MIC} \geq 2 \mu\text{g/mL}$  were unlikely to be exposed to sufficient gentamicin for effective killing. Approximately 90% of isolates from ambulatory practice and 36% of hospital isolates had MICs at or below breakpoints for susceptibility with most of the remainder unlikely to be responsive, even to higher IV doses.

**Conclusions and Clinical Importance:** Gentamicin at a dosage of 6.6 mg/kg IV is likely to be effective against the majority of infections encountered in ambulatory practice, but less effective in an equine hospital. Because there was a dichotomy of most bacteria as being clearly susceptible or clearly resistant to gentamicin, it appears unlikely that higher doses would have been more efficacious, especially in the hospitalized population in our study.

## Conclusion:

"it is difficult to justify MIC breakpoint recommendations  $>2$   $\mu\text{g/mL}$ , at least in this population of horses. This conclusion is consistent with CLSI equine-specific recommendations indicating that for Enterobacteriaceae, *Pseudomonas aeruginosa*, and *Actinobacillus pleuropneumoniae*,  $\text{MIC} \leq 2$   $\mu\text{g/mL}$  should be taken to indicate probable susceptibility, although possible susceptibility (intermediate) is attributed to bacteria with MIC of 4  $\mu\text{g/mL}$ ."

## Concentrations and bacterial susceptibility

Minimum inhibitory concentration (MIC) data allow  
comparison of serum gentamicin concentrations in horses  
to the MIC of gentamicin of bacteria for which

retrospective analysis of hospital records. Peak and trough plasma gentamicin concentrations were determined after 6.6 mg/kg gentamicin IV in 339 hospitalized horses. The MIC of gentamicin was determined for 503 isolates from ambulatory practice and 33 from hospital practice. Gentamicin concentrations and MIC results were compared to current recommendations for breakpoints.

Minimum gentamicin concentration at 60 minutes after administration ( $C_{60\text{min}}$ ) was compared to MIC distribution indicating that bacteria with  $\text{MIC} \geq 2$   $\mu\text{g/mL}$  were unlikely to be exposed to gentamicin for effective killing. Approximately 90% of isolates from ambulatory practice and 100% of hospital isolates had MICs at or below breakpoints for susceptibility with most of the isolates likely to be responsive, even to higher IV doses.

**Conclusions and Clinical Importance:** Gentamicin at a dosage of 6.6 mg/kg IV is likely to be effective against the major bacterial infections encountered in ambulatory practice, but less effective in an equine hospital. Because there was a dichotomy of most bacteria as being clearly susceptible or clearly resistant to gentamicin, it appears unlikely that higher doses would have been more efficacious, especially in the hospitalized population in our study.

## Conclusion:

[citing other studies] "Neither study supported the use of gentamicin at a dosage of 6.6 mg/kg IV for the treatment of infections caused by bacteria with MIC  $\geq 4$   $\mu\text{g/mL}$ , and it seems inconceivable that success could be obtained against bacteria with MIC  $\geq 8$   $\mu\text{g/mL}$ . This conclusion concurs with CLSI recommendations that bacteria with MIC  $\geq 8$   $\mu\text{g/mL}$  should be regarded as resistant and that those with MIC 4  $\mu\text{g/mL}$  as having intermediate sensitivity suggesting therapeutic success might only be possible using higher dosages or when infection is at sites of drug accumulation (eg, urine)."

## Concentrations and bacterial sensitivity

Minimum inhibitory concentration (MIC) data allow

for serum gentamicin concentrations in horses  
to be compared to the MIC of gentamicin of bacteria for which

and trough plasma gentamicin concen-  
trations were determined in 339 hospitalized horses. The MIC of  
gentamicin for practice and 33 from hospital practice.  
Results were compared to current recom-

ended at 60 minutes after administration ( $C_{60\text{min}}$ )  
for bacteria with MIC  $\geq 2$   $\mu\text{g/mL}$  were unlikely to  
be effective. Approximately 90% of isolates from ambu-

latory practice and 36% of hospital isolates had MICs at or below breakpoints for susceptibility  
with most of the remainder unlikely to be responsive, even to higher IV doses.

**Conclusions and Clinical Importance:** Gentamicin at a dosage of 6.6 mg/kg IV is likely to be  
effective against the majority of infections encountered in ambulatory practice, but less effective  
in an equine hospital. Because there was a dichotomy of most bacteria as being clearly susceptible  
or clearly resistant to gentamicin, it appears unlikely that higher doses would have been more effi-  
cacious, especially in the hospitalized population in our study.

Rifampin	Dogs, Horses	<ul style="list-style-type: none"><li>• PK data available for horses, but scarce for dogs.</li><li>• PK-PD targets need to be defined.</li></ul>

# Generic Drug Working Group

## New Breakpoints

Agent	Species	Status
Other 3 <sup>rd</sup> -Generation Cephalosporins?	Dogs, Cats, Horses	✓ Ceftazidime • Cefotaxime
Carbapenems?	Dogs, Cats	• PK data available • PK-PD targets defined • Just use human breakpoint?
Tylosin	Cattle, Pigs	• Collecting data and PK-PD targets
Amoxicillin, Amoxicillin-Clavulanate	Cat-urine	• Studies are planned to collect data

Table 2A. *Enterobacteriaceae* (Continued)

Test/ Report Group	Body Site	Antimicrobial Agent	Organism	Disk Content	Interpretive Categories and Zone Diameter Breakpoints, nearest whole mm			Interpretive Categories and MIC Breakpoints, µg/mL			Comments
					S	I	R	S	I	R	
Aminoglycosides/Aminocyclitols (Continued)											
Humans											
(10) Warning: For <i>Salmonella</i> spp. and <i>Shigella</i> spp., aminoglycosides may appear active <i>in vitro</i> but are not effective clinically and should not be reported as susceptible.											
		Amikacin		30 µg	≥17	15–16	≤14	≤16	32	≥64	
		Gentamicin		10 µg	≥15	13–14	≤12	≤4	8	≥16	
		Kanamycin		30 µg	≥18	14–17	≤13	≤16	32	≥64	
		Streptomycin		10 µg	≥15	12–14	≤11	–	–	–	(11) There are no MIC breakpoints.
Penicillins											
Dogs											
A	Skin, soft tissue	Ampicillin	<i>E. coli</i>	–	–	–	–	≤0.25	0.5	≥1.0	(12) Systemic breakpoints were derived from microbiological and PK-PD data. The dosage regimen used for PK-PD analysis of amoxicillin was 22 mg/kg every 12 hours orally.  (13) Except for lower UTI, <i>E. coli</i> and other <i>Enterobacteriaceae</i> will test resistant to ampicillin and amoxicillin.
A	UTI	Ampicillin	<i>E. coli</i>	–	–	–	–	≤8	–	–	(14) This breakpoint for UTIs was derived from published literature in which orally administered ampicillin 25.6 mg/kg and amoxicillin 11 mg/kg was administered to healthy dogs at 8-hour intervals for 5 consecutive doses and produced urine concentrations in dogs > 300 µg/mL.

Table 2A. *Enterobacteriaceae* (Continued)

Test/ Report Group	Body Site	Antimicrobial Agent	Organism	Disk Content	Interpretive Categories and Zone Diameter Breakpoints, nearest whole mm			Interpretive Categories and MIC Breakpoints, µg/mL			Comments
					S	I	R	S	I	R	
Penicillins (Continued)											
Cats											
A	Skin, soft tissue, UTI	Ampicillin	<i>E. coli</i>	—	—	—	—	≤0.25	0.5	≥1.0	(15) Ampicillin breakpoints were determined from an examination of MIC distribution data and PK-PD analysis of amoxicillin in cats. The dosage regimen used for PK-PD analysis of amoxicillin was 12.5 mg/kg administered every 12 hours orally.
